## PRIORITY DOCUMENT

SUBMITTED OR TRANSMITTED IN  
COMPLIANCE WITH RULE 17.1(a) OR (b)

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that the attached copy of the request for grant of a Patent (Form 1/77) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

Dated 3 February 2004

**Warning**

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

**Notes**

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there is not enough space for all relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- d) If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- e) Once you have filled in the form you must remember to sign and date it.
- f) For details of the fee and ways to pay, please contact the Patent Office.

TREATMENT OF CHEMICAL WASTE

This invention relates to the treatment of toxic and/or environmentally hazardous or harmful materials and more especially to the treatment of exhaust gases arising from various chemical processes.

5       The chemical processing industry in general generates vast quantities of by-products and waste materials many of which represent environmental hazards and which must be neutralised or destroyed as an essential part of their ultimate disposal. The oil and gas processing industries, for example, invest heavily in plant and equipment designed specifically to prevent or  
10      minimise the release of harmful largely organic materials into the environment. The microelectronics and semi-conductor device manufacturing industries for example make similar investments in order to scrub or otherwise treat exhaust gas streams containing generally inorganic materials from chemical processing units prior to the release of those exhaust gases into  
15      the atmosphere. Compounds containing heavy metals and halogen-, sulphur-, phosphorus- and nitrogen- containing compounds can be especially toxic and their removal is the subject of a considerable amount of technical research and of much environmental protection legislation.

In many cases even dilute solutions or suspensions of such hazardous  
20      materials cannot be legally discharged. For example, the legal limit for aqueous HF discharge can be as low as 3 ppm. Nevertheless, huge quantities of not only HF but also other aqueous acids such as HCl, HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> continue to be generated by traditional scrubbing and other absorption

systems. The discharge of such aqueous acids therefore involves the use of enormous quantities of fresh water to restrict acid concentration. For example, a closed loop scrubbing system for absorbing HF from an exhaust gas, operating at a recirculation rate of 25 l/min, will generally consume about 5 6 l/min of fresh water in order to maintain fluoride ion concentrations at an acceptably low level in the recirculating water. This discharge concentration can be as high as 4000 ppm in which case significant further dilution or treatment will be necessary.

10 Ion exchange techniques offer an alternative route for the capture and eventual disposal of many toxic and other hazardous materials. However, many ion exchange materials are insufficiently selective to be truly efficient. Additionally, an ion exchange material that is loaded with captured ions must be regenerated by back-washing which in turn involves the use of further potentially hazardous chemical species.

15 A more recent development is that of a technique known as electrochemical deionisation which is described in European Patent No. 680932. Briefly, that technique involves the use of a combination of an electrochemical cell and an ion absorbing material in which ions captured on the absorbing material are transported through that material under the 20 influence of an applied electric field to emerge in an eluate zone whence they are removed. That procedure appears to have a good efficiency but is described in the context of the solution to be treated making only a single pass through the electrochemical deionisation device.

5       The present invention seeks to provide a method which is capable of continuously removing anionic and/or cationic species from an aqueous solution circulating in a closed loop system, such as that referred to above incorporating a gas scrubbing unit, without the need for regeneration or other chemical or physical revitalisation of the separation medium.

This is achieved by means of the invention by continuously flowing an aqueous solution containing anions and/or cations derived from a gaseous exhaust system and present in a closed loop circulation system including the gas scrubbing unit, over one surface of a water permeable layer of an ion 10 absorbing material while applying an electrical potential across the thickness of that layer.

Accordingly, the present invention provides in a first aspect a method for the treatment of gaseous chemical waste which comprises the steps of:

15       continuously circulating water through an essentially closed loop incorporating a gas scrubbing unit and an ion absorption unit comprising a water permeable layer of an ion absorbing material;

feeding exhaust gas or a reaction product thereof to the gas scrubbing unit for dissolution in the circulating water thereby to form an aqueous solution containing ionic species derived from the exhaust gas;

20       continuously passing the circulating water over one surface of the layer of ion absorbing material in the ion absorption unit while applying an electrical potential across the thickness of that layer and removing from the ion absorption unit via the other surface of that layer a more concentrated

aqueous solution of the ionic species; and

continuously adding to the closed loop a quantity of water corresponding to the quantity of aqueous solution of the ionic species removed from the ion absorption unit.

5 The present invention provides also in a second aspect apparatus for use in carrying out such a method, comprising

an essentially closed loop circulation system containing a gas scrubbing unit and an ion absorption unit comprising a water permeable layer of an ion absorbing material and means for enabling an electrical potential to be applied 10 across the thickness of that layer;

a pump for continuously circulating water around the closed loop;

an inlet for exhaust gas or a reaction product thereof into the gas scrubbing unit:

an inlet for water into the closed loop circulation system; and

15 an outlet for a concentrated aqueous solution of ionic species from the ion absorption unit.

The apparatus may include also within the closed loop circulation system one or more heat exchangers and/or filters, hydrocyclones and similar devices to remove from the circulating solution any particulate/suspended 20 solid matter.

The exhaust gas is the gaseous effluent or by-product(s) from any production procedure and the safe disposal of which or of a component of which is to be achieved. If the exhaust gas or the relevant component thereof

is in a form suitable for dissolution in water and for subsequent treatment according to the method of the invention, then preliminary treatment of the exhaust gas may be unnecessary. For example, when the exhaust gas itself contains oxides of phosphorus, the gas scrubbing unit serves to effect  
5 dissolution of those oxides of phosphorus to produce aqueous phosphates and/or phosphites.

In the alternative, when the exhaust gas contains water-insoluble materials such as fluorocarbons or CFCs, it will be necessary to employ a combustor, plasma reactor or other reaction unit in order to convert those  
10 water-insoluble materials into water-soluble form. Fluorocarbons, for example, may be converted into HF in this manner, and HF dissolves readily in water in the gas scrubbing unit to generate hydrofluoric acid.

The ion absorbing material serves to capture the ions of interest and is preferably an ion exchange material such as an ion exchange resin in the form  
15 of particles or beads. The particles or beads of the resin are preferably in a coherent form, that is to say they are not mobile or loose, but are constrained in a predetermined configuration. For example, the particles or beads may be bound together with a binder or held between layers of a mesh or membrane, so as to be permeable to the aqueous solution containing the ions. The  
20 electrical potential which is applied across the thickness of the layer of ion absorbing material serves to drive the captured ions through the ion absorbing material from the surface at which they are captured, i.e. the surface in contact with the flow of aqueous solution containing the ions, to the opposite surface

from which the ions are eluted. The electrical potential may be generated from a pair of electrodes arranged to form an electrolysis cell or by any alternative arrangement, for example in the form of an electrophoresis cell.

It has been found that using the method and apparatus according to the  
5 invention, it is possible to effect continuous separation of anions and/or cations within a closed loop circulation system such as that used for gas scrubbing, without any need for regenerating or periodically replacing the ion absorbing material. The efficiency of the method and apparatus will depend upon the nature of the ion absorbing material and of the ion or ions to be  
10 captured, the concentration of the ion or ions in the solution and other factors such as flow rates and electrical potential but initial indications are that ion extraction rates of up to 98% per pass can be achieved.

With such high extraction rates, the removal of acid cations such as F<sup>-</sup>, SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup> will have a dramatic effect upon improving the service life of  
15 the equipment in the circulation system, such as pumps, meters, valves and baffles.

The method of the invention is applicable to a wide variety of cationic species such as sulphate, sulphite, nitrate, nitrite, phosphate, phosphite and halides, that is to say fluoride, chloride, bromide and iodide, as well as anionic  
20 species, especially metals and more especially heavy metals.

The invention does, however, have particular applicability to fluoride such as that generated as a by-product of the semi-conductor manufacturing industry and which produces aqueous hydrofluoric acid as a result of reaction

followed by dissolution in a gas scrubbing unit.

It has unexpectedly been found that the ions stripped from the aqueous solution in the method of the invention do no re-enter the aqueous circulation stream that continues to flow across the surface of the ion absorbing material.

5      This is an especially important feature of the invention since although the gas scrubbing operation will generally be carried out on a continuous basis, the acid content of the gas entering the scrubber may be variable and may often be totally absent. This means that the fluoride ion content of the water passing across the surface of the ion absorbing material is correspondingly  
10     variable. The fact that the captured ions are transported away from the surface of the ion absorbing material under the influence of the applied electrical potential removes those ions from being resolubilised by the water. This represents a significant improvement in ion absorption efficiency.

Compared to the example given above of a closed loop gas scrubbing  
15     system resulting in aqueous HF operating at a recirculation rate of 25 l/min and consuming about 6 l/min fresh water, a similar system incorporating the features of the present invention has been shown in initial trials to be capable of achieving up to a 30-fold reduction in the fresh water requirement.

The invention is described below in greater detail by way of example  
20     only with reference to the accompanying drawings, in which:

Fig. 1 is a schematic representation of a closed loop recirculation gas treatment apparatus known from the prior art;

Fig. 2 is a schematic representation of a closed loop recirculation gas

treatment apparatus according to the invention; and

Fig. 3 is a schematic representation of an example of an electrochemical cell which may be used in the apparatus shown in Fig. 2.

Referring to the drawings, in Fig. 1 there is shown a schematic representation of a conventional gas treatment unit for exhaust gases from a semi-conductor device manufacturing plant. The exhaust gases may contain many and varied species including halogen-, phosphorus-, silicon- and boron-containing compounds. The exhaust gases or the products of their preliminary reaction, for example HF in the case of flourine-containing compounds, enter the gas scrubbing unit 3 through line 4 where they are brought into intimate contact with water entering through line 2. Line 2 forms part of a closed loop circulation system 1 which includes a pump 5 for the forced circulation of water around the loop, together with a line 6 through which aqueous HF can be drained from the system and a line 7 through which corresponding amounts of fresh water may be admitted to the loop. The circulation system 1 may also include one or more other conventional items, for example filters, hydrocyclones, heat exchangers, meters, gauges and valves. The gas scrubbing unit 3 will contain packing, baffles, cyclones and/or similar means, to optimise liquid/gas surface contact in order to promote dissolution of gas in the aqueous liquid; such scrubbing technology is well known in the art and does not need to be separately described here.

In an example of conventional operation, 200 slpm of an exhaust gas containing 2,000 sccm  $C_2F_6$  is stoichiometrically converted into HF (12,000

sccm HF) which enters the gas scrubbing unit 3 through line 4 and contacts water entering through line 2 at a rate of 25 l/min and is dissolved in that water. Up to 400 ppm HF will usually be dissolved in the aqueous stream in this way although concentrations as high as 4000 ppm HF can be achieved by  
5 higher input gas flows and prolonged recirculation of the liquid. Undissolved gas is typically discharged from the scrubber to the atmosphere. Fresh water is admitted to the loop through line 7 at a rate of 6 l/min and aqueous acid is withdrawn through line 6 at a corresponding rate. The withdrawn acid will have a HF content dependent upon gas input and will  
10 present serious problems of disposal.

Referring now to Fig. 2, the system shown is in accordance with the invention and is generally similar to that shown in Fig. 1 in that the closed loop 1 includes a gas scrubbing unit 3 and a pump 5. In this case, however, the loop incorporates also an acid removal unit 8. An example of a suitable  
15 acid removal unit is described in greater detail below but in one trial was shown to be capable of generating 0.15 l/min (approximately 200 l/day) aqueous 0.73M HF from a continuous input at 25 slpm of 400 ppm HF giving a continuous liquid output at 11 ppm HF. As a consequence, the aqueous liquid entering the gas scrubbing unit contains much less dissolved HF,  
20 thereby rendering HF absorption in the gas scrubbing unit more efficient. Also, the HF concentration in the circulating liquid in the loop can be maintained at a lower level than hitherto, thereby improving the service life of the equipment. Moreover, the reduced volume of generated material, in this

case 0.73M hydrofluoric acid is usable as such and its disposal does not therefore present a problem.

Turning now to Fig. 3 of the drawings, there is shown an example of an electrochemical cell suitable for incorporation into the closed loop of the apparatus shown in Fig. 2, for separating HF from the circulating acid solution. The cell is in fact very similar to that described in European Patent No. 0680932 referred to above.

The electrochemical cell 10 shown in Fig. 3 of the drawings comprises an electrode assembly 11 and a housing 21 which together define a compartment 12. The electrode assembly 11 comprises a current feeder 13 in contact with an electrode contact 20 and is embedded in a permeable layer 14 of particulate ion exchange resin bound together with a binder within a housing 15 and presenting front and rear surfaces 16 and 17. The rear surface 17 is adjacent but slightly spaced from a wall of the housing 15 which in turn includes a vent 18 and an elution port 19. The housing 21 includes an inlet 24 and an outlet 25 for the circulating aqueous liquid and includes a counter electrode 26 in contact with an electrode contact 27.

In order to remove fluoride and nitrate ions from the circulating liquid in the closed loop system, the permeable layer 14 will include a weak anion exchange resin. The circulating solution of fluoride and nitrate passes through compartment 12 via the inlet 24 and outlet 25 and within the cell it contacts the front surface 16 of the ion exchange layer 14 and the counter electrode 26. An electric potential between the feeder 13 (anode) and the

\* counter electrode 26 (cathode) generates H<sup>+</sup> at the feeder 13. Those hydrogen ions move towards the counter electrode 26 and interact with and activate the anion exchange resin in the layer 14. The fluoride and nitrate ions in the solution move into the layer 14 where they are adsorbed onto the activated ion exchange resin and in which they move under the influence of the applied potential towards the rear surface 17. This enables more fluoride and nitrate ions to be adsorbed at the front surface 14 to permit continuous removal of those ions from the aqueous solution circulating through cell 10. Water from the solution also permeates the layer 14 and flows towards the rear surface 17 whence it and the captured fluoride and nitrate ions collect to be removed through the elution port 19 as aqueous hydrofluoric/nitric acid.

CLAIMS:

1. A method for the treatment of gaseous chemical waste which comprises the steps of:

5 continuously circulating water through an essentially closed loop incorporating a gas scrubbing unit and an ion absorption unit comprising a water permeable layer of an ion absorbing material;

10 feeding exhaust gas or a reaction product thereof to the gas scrubbing unit for dissolution in the circulating water thereby to form an aqueous solution containing ionic species derived from the exhaust gas;

15 continuously passing the circulating water over one surface of the layer of ion absorbing material in the ion absorption unit while applying an electrical potential across the thickness of that layer and removing from the ion absorption unit via the other surface of that layer a more concentrated aqueous solution of the ionic species; and

continuously adding to the closed loop a quantity of water corresponding to the quantity of aqueous solution of the ionic species removed from the ion absorption unit.

20 2. A method according to claim 1, wherein the exhaust gas or the reaction product thereof is fed continuously to the gas scrubbing unit.

3. A method according to claim 1, wherein the exhaust gas or the

reaction product thereof is fed intermittently to the gas scrubbing unit.

4. A method according to any one of claims 1 to 3, wherein the exhaust gas or the reaction product thereof contains HF and the ionic species is F<sup>-</sup>.

10

5. A method according to any one of claims 1 to 4, wherein the exhaust gas or the reaction product thereof contains HC1 and the ionic species is Cl<sup>-</sup>.

6. A method according to any one of claims 1 to 5, wherein the exhaust gas or the reaction product thereof contains oxides of nitrogen and the ionic species is NO<sub>3</sub><sup>-</sup>.

15

7. A method according to any one of claims 1 to 6, wherein the exhaust gas or the reaction product thereof contains oxides of sulphur and the ionic species is SO<sub>4</sub><sup>2-</sup>.

20

8. A method according to any one of claims 1 to 7, wherein the exhaust gas or the reaction product thereof contains oxides of phosphorus and the ionic species is PO<sub>4</sub><sup>3-</sup>.

9. Apparatus for use in carrying out the method of claim 1,

comprising

an essentially closed loop circulation system containing a gas scrubbing unit and an ion absorption unit comprising a water permeable layer of an ion absorbing material and means for enabling an electrical potential to be applied across the thickness of that layer;

5 a pump for continuously circulating water around the closed loop;

an inlet for exhaust gas or a reaction product thereof into the gas scrubbing unit;

an inlet for water into the closed loop circulation system; and

10 an outlet for concentrated aqueous solution of ionic species from the ion absorption unit.

10. Apparatus according to claim 9, which comprises also within the closed loop circulation system one or more heat exchangers, filters and/or  
15 hydrocyclones.
